

How the Session Works

Outline

- Practical on arrival
- Talk 1
 - Reflect on practical
 - Clarify concepts
- Practical exercises at your own pace
- Talk 2:
 - Further concepts
 - Overall reflection
- *Continue practical exercises at home*

Getting Started

- Log-on
- Find portable Python on L:\ drive
- Start IDLE
- Find resources on teachinglondoncomputing.org
 - Exercise sheet (and notes) – ***START NOW***
 - Example programs
 - Slides

First Program – Click the Button

- Code provided but not yet explained
- Use ‘pattern matching’ (i.e. intelligent guessing) to modify it

Teaching **L**ondon **C**omputing

A Level Computer Science

Programming GUI in Python

William Marsh
School of Electronic Engineering and Computer Science
Queen Mary University of London

Outline

- A first program
 - Concepts in **Graphical User Interface**
 - Components / widgets and attributes
 - Events / actions
 - Layout
 - *Practical examples*
 - Challenges of GUI programming
 - Choosing a GUI library
 - Using Object-Oriented programming
-

Key Concepts

Explained Using the Button Example

Key Concepts

- A widget / component
 - E.g. a button, a frame
 - Attributes e.g. the button text
 - Actions
 - E.g. what happens when you press the button
 - Layout
 - Positioning widgets
-

AppInventor

The screenshot shows the AppInventor interface with the following components:

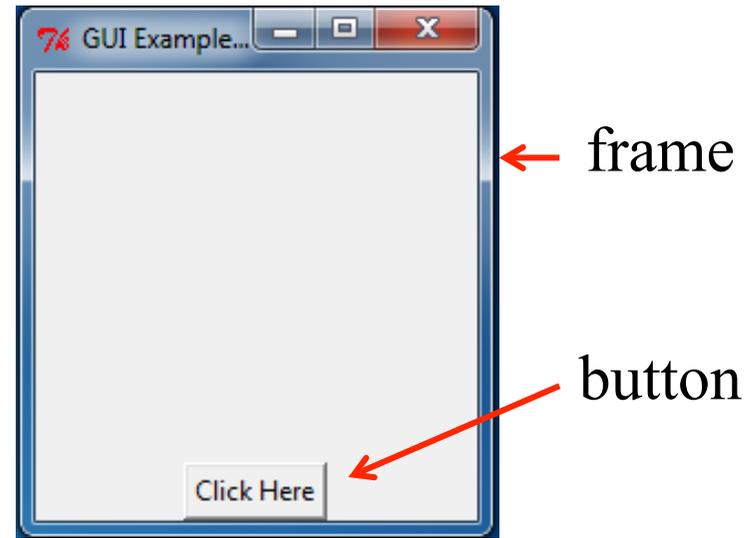

- Palette:** A list of widgets including Button, Canvas, CheckBox, Image, Label, ListPicker, PasswordTextBox, TextBox, and TinyDB.
- Viewer:** A central workspace showing a mobile screen layout with a title bar (5:09 PM), a screen header (Screen1), and two text labels (Text for CheckBox1 and Text for Button1).
- Components:** A tree view showing the hierarchy of components: Screen1 (containing CheckBox1 and Button1).
- Properties:** A panel showing the attributes of the selected component (Screen1), such as BackgroundColor (White) and Title (Screen1).

Four red callout boxes with white text are overlaid on the interface:

- Code for events:** Points to the bottom of the Viewer area.
- Widgets, called components:** Points to the Palette area.
- Hierarchy of components:** Points to the Components tree view.
- Attributes called properties:** Points to the Properties panel.

Widgets

- A GUI is made up from widgets
- A widget is created
- Widget has attributes
- One widget may contain another:
 - Frame contains the button

Create a Widget

- Constructor
 - Name same as widget
 - Hierarchy of widget
 - Optional arguments

```
# Create a main frame with
#     - a title
#     - size 200 by 200 pixels
app = Tk()
app.title("GUI Example 1")
app.geometry('200x200')
```

Constructor

Parent
widget

Optional
argument

```
# Create the button
#     - with suitable text
#     - a command to call when the button is pressed
button1 = Button(app, text="Click Here", command=clicked)
```

Widgets have Attributes

- E.g. a name, size
- Any property of the widget that makes it specific

```
# Create a main frame with
#     - a title
#     - size 200 by 200 pixels
app = Tk()
app.title("GUI Example 1")
app.geometry('200x200')
```

Attributes set by
constructor (note use of
keyword arguments)

Methods to
set attributes

```
# Create the button
#     - with suitable text
#     - a command to call when the button is pressed
button1 = Button(app, text="Click Here", command=clicked)
```

How to Set / Get an Attribute

- Method 1 (setting):
 - Set value with the constructor
- Method 2 (setting and getting):
 - Widget is a dictionary

```
# Change button text  
mText = button1['text']  
button1['text'] = mText.upper()
```

- Method 3 (sometimes)
 - Call a suitable method

Other
methods exist

Aside: Dictionaries

- Dictionary: a map from a key to a value
 - Unique key
 - Built in (Python) versus library (many other languages)

Standard Array	Python Dictionary
Index by number	Key can be a string, pair, ...
Indices continuous e.g. 0 → 10	Gaps ok
Holds only number, character	Any value – even a dictionary

```
# Change button text
```

```
mText = button1['text']
```

```
button1['text'] = mText.upper()
```

Lookup

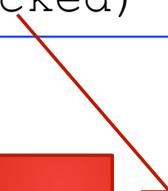

Update

Handle an Event

```
# This method is called when the button is pressed
def clicked():
    print("Clicked")

# Create the button with
#   - a command to call when the button is pressed
button1 = Button(app, text="Click Here", command=clicked)
```

- Events
 - Button, mouse click, key press
- Action
 - Event 'bound' to function

Name of a
Method

Layout the Widget

```
# Make the button visible at the bottom of the frame  
button1.pack(side='bottom')
```

- Where does the widget go?
 - Hierarchy
 - Top-level window
 - Layout manager
 - Several available
 - Problem of resizing
 - The 'pack' layout manager is simplest
 - *Widget is not visible until packed*
-

A Minimal Application

```
# Import the Tkinter package
# Note in Python 3 it is all lowercase
from tkinter import *

# Create a main frame
app = Tk()

# Start the application running
app.mainloop()
```

Loop to
handle events

import with
prefix

```
# Import the Tkinter package
# Note in Python 3 it is all lowercase
import tkinter as tk

# Create a main frame
app = tk.Tk()

# Start the application running
app.mainloop()
```

(Some) tkinter Widgets

Widget	Use
Button	A button
Canvas	For drawing graphics
Entry	Entry a line of text
Frame	A rectangular area containing other widgets
Label	Display a single line of text
Menu	A set of options shown when on a menu bar
Radiobutton	Select one of a number of choices
Scrollbar	Horizontal or vertical scrolling of a window
Text	A multi-line text entry
<i>Toplevel</i>	<i>A top-level frame</i>

Further Practical Exercises

- See exercise sheet
- A sequence of exercises introduce other widgets and apply the core concepts
- ... probably too many to finish now

You may also need to refer to the notes at the end

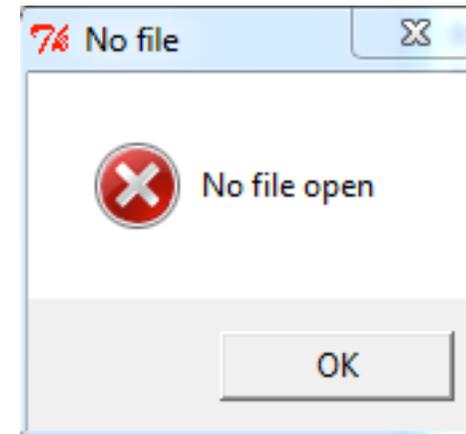

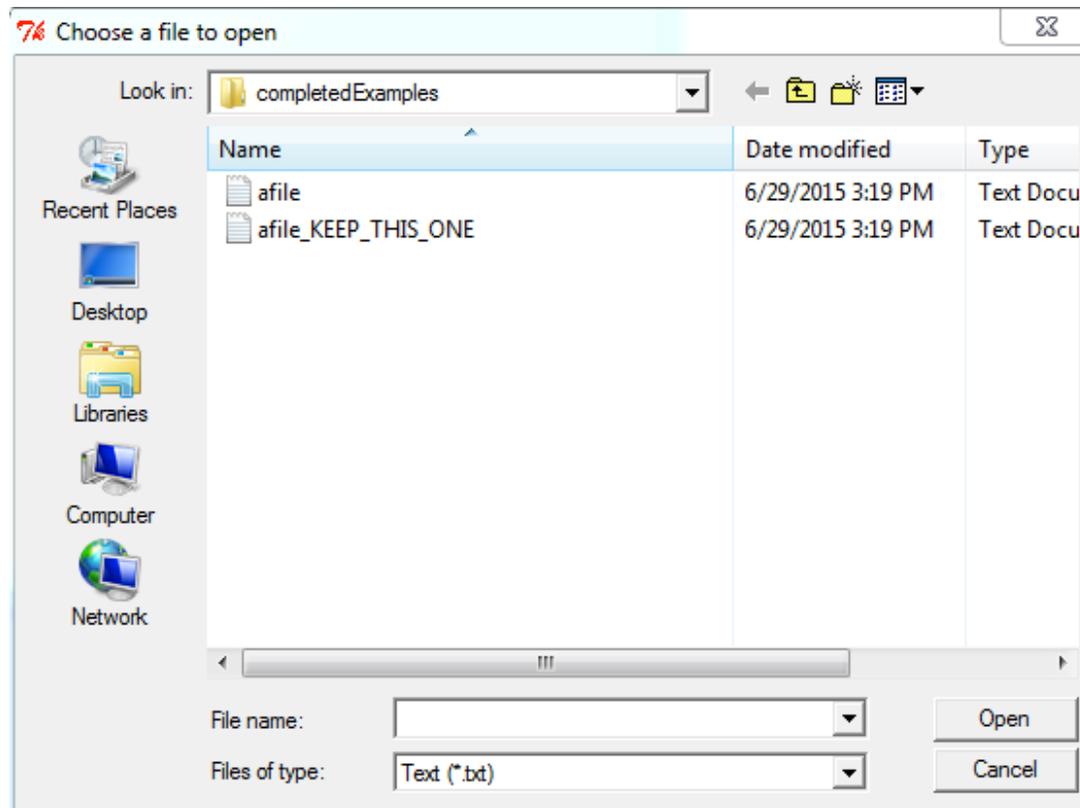

Further Concepts

- Dialog
 - Top-level window
 - Control variables
-

Dialogs

- You must respond to a dialog
 - Messages
 - File choosing

Top-Level Windows

- At least one top-level window
 - Conveniently created using `Tk ()`
 - Like a frame but ...
 - Menu bar
 - Standard buttons
 - Borders
-

Control Variables

- Variables linking
 - Entry widget to its text
 - Choices in a RadioButton
 - These are objects in the framework
-

Challenges in GUI

- *Which framework?*
 - *How to design a GUI*
 - *How much OOP?*
-

GUI Framework

- A GUI framework defines a set of widgets
 - Windows has its own GUI framework
 - Python uses a portable GUI framework
 - tkinter, depends on Tk and TCL
 - PyQt, depends on QT
 - Tkinter
 - Pro: simple, easy to install
 - Cons: a bit limited; documentation weak
 - PyQt: more complex
-

Designing a GUI

- What am I trying to do?
 - What widgets do I need?
 - Where will they go?
 - How do they behave?
-

The OOP Problem

- Why OO and GUI
 - Widgets are classes
 - Default behaviour
- GUI programs are often organised using classes

```
#!/usr/bin/env python      1
import Tkinter as tk      2

class Application(tk.Frame):  3
    def __init__(self, master=None):  4
        tk.Frame.__init__(self, master)  5
        self.grid()

    def createWidgets(self):
        self.quitButton = tk.Button(self, text='Quit',  6
                                     command=self.quit)  7
        self.quitButton.grid()

app = Application()      8
app.master.title('Sample application')  9
app.mainloop()          10
```

- **Practical Problem: most examples use OOP**
-

Summary

- Core concepts common to all framework
 - Understand principles
 - Learn about available widgets
 - Look up attributes and methods

 - After programming ... interface design
-
